16. ABSTRACT This report presents ground-level runway wind statistics for the Edwards AFB, California area. Crosswind, headwind, tailwind, and headwind reversal percentage frequencies are given with respect to month and hour for the two major Edwards AFB runways. Also presented are Edwards AFB bivariate normal wind statistics for a 90 degree flight azimuth for altitudes 0 through 27 km. Wind probability distributions and statistics for any rotation of axes can be computed from the five given parameters: $\bar{u}$, $\bar{v}$, $S(u)$, $S(v)$, and $R(uv)$. This document supersedes NASA TM-78136 and should be used in place of it.

FOREWORD

This revised document was required because of data tape problems which led to errors in the ground wind tables of NASA Technical Memorandum 78136, September 1977. This document corrects and supersedes NASA TM-78136. In addition, headwind component cumulative percentage frequency statistics have been included in this document.

TECHNICAL MEMORANDUM 78160

GROUND WINDS AND WINDS ALOFT FOR EDWARDS AFB,
CALIFORNIA (1978 REVISION)

I. INTRODUCTION

This two-part report deals with wind conditions over Edwards AFB, California, including the NASA Dryden Flight Research Center. Since the first four orbital flight tests of the Space Shuttle mission schedule Orbiter landings at Edwards AFB, these wind statistics may prove useful in mission planning activities. The first part of this report presents low-level crosswind, headwind, tailwind, and headwind reversal statistics by hour and month for two different Edwards AFB runway orientations. The second part gives bivariate normal wind statistics for altitudes 0 through 27 km by monthly reference periods. This document supersedes NASA TM-78136 and should be used in place of it.

II. ARRANGEMENT OF TABLES

Tables are numbered and arranged by monthly reference period, with subnumbers used to identify the crosswind, tailwind, headwind, or reversal statistics within each month as follows:

Section III

Crosswind: Tables 1.1 through 13.1

Tailwind: Tables 1.2 through 13.2

Crosswind versus Tailwind: Tables 1.3 through 13.3

Headwind Reversals: Tables 1.4 through 13.4

Headwind: Tables 1.5 through 13.5

Section IV

Bivariate Normal Wind Statistics: Tables 1.6 through 12.6

III. RUNWAY CROSSWINDS, TAILWINDS, AND HEADWIND REVERSALS

A. Background

A study similar to the one presented here was done for the NASA/Kennedy Space Center (KSC), Florida, area in October 1972 [1]. The KSC study used hourly peak ground wind data to determine optimum runway orientation by minimizing critical high crosswind component frequencies. The proposed runway orientation was then used in conjunction with the hourly peak wind data to determine frequencies of headwind-to-tailwind reversals that resulted in specified tailwind speeds. The present Edwards AFB wind study expands on the two types of information determined previously for KSC and adds a section on tailwinds alone.

B. Runway Orientation

The two main Edwards AFB runways of interest for NASA Shuttle Orbiter landings are runways 17-35 (170-350 degrees) and 22-4 (220-40 degrees). Figure 1 is an artist's conception of the Space Shuttle Orbiter making its final approach (toward the south) onto Edwards AFB runway 17 after completing a space mission. An F-104 jet aircraft is also shown escorting the Orbiter. Figure 2 indicates the general layout of the two main runways. The runways are designated 17-35 and 22-4 because of their angle of separation in degrees clockwise from magnetic north, and they indicate a pilot's approach toward that direction. That is, a pilot desiring to land toward the south on 17-35 would enter from the north end (17), thereby allowing him to land toward 170 degrees. These two runway orientations with respect to true north are approximately 190-10 (for 170-350 magnetic) and 239-59 (for 220-40 magnetic). All magnetic runway wind statistics given in this report were computed with respect to true north.

The two runways are oriented so that a vehicle landing from the northeast toward the southwest will probably be landing into a headwind. Figure 3 [2] gives the prevailing surface wind direction versus hour and month. The respective percentages of the prevailing direction are given within each box. Southwesterly winds tend to prevail from late evening hours until midday and give way to west-southwesterly flow during the afternoon until late evening hours. Some westerly flow prevails, except near midday, during the winter months. Mean surface wind speeds (in knots) versus hour and month are given in Figure 4 [2]. It can

be noticed that wind magnitudes generally pick up during the afternoon hours [1500-1700 local standard time (LST)], with larger magnitudes observed during the summer months.

C. Data Used

The ground wind speed and direction data used in this study were taken from two magnetic tapes containing the Edwards AFB WBAN hourly surface observations (deck No. 144) [3]. The period of record extended from 1949 to

ORIGINAL PAGE IS
OF POOR QUALITY

EDWARDS AFB P.O.R. DEC. 41 - JULY 72
3 h INTERVALS (LST)

Figure 4. Edwards AFB mean surface wind speed (knots).

1970. The combined tapes give a total of 192,782 hourly observations for Edwards AFB. All calms were included in the data sample. During the period of record the anemometer location was changed several times. However, most of the observations were made approximately 4 m (13 ft) above natural grade.

The data used in this study were obtained from averaged¹ observations taken on the hour. The method of using average wind conditions differs from the peak wind method used in the earlier KSC study [1]. In Space Shuttle vehicle

1. Standard WBAN practice, generally a 1 min average about the hour.

ground wind related analyses, peak wind speeds (or gusts) are generally more useful in design, mission planning, and operational activities. However, since no peak wind climatic data were available for the Edwards AFB area, the hourly observations described previously were used to make the required computations. The steady-state wind speed statistics given in this report can be adjusted to approximate peak wind speed statistics by multiplying the steady-state winds by 1.4. Graves [4] describes a method that enables one to estimate peak winds from hourly observations. The reader should consult Reference 4 for further discussion of these types of estimation methods.

D. Computational Methods/Equations

1. Crosswind Procedure. This section includes a discussion of the computational methods used in obtaining the percentage frequency of occurrence within critical crosswind intervals, i.e., 1-4, 5-9, 10-14, 15-19, 20-24, and 25-up knots. The crosswind equation used for each runway is:

$$\text{Crosswind} = (\sin | \text{WD} - \text{RA} | \times \text{WS}) \quad (1)$$

where

RA = runway angle measured from true north

WD = wind direction in degrees clockwise from true north

WS = wind speed in knots.

The runway crosswind component for each observation was computed and then checked against the several critical crosswind intervals, and a tally was entered into the appropriate matrix position. Every wind observation (192,782 total observations) was handled in this manner.

The percentage frequency of occurrence of crosswind components within these critical intervals was next calculated for each matrix position by dividing the total number in that position by the total number of observations and multiplying by 100; i.e.,

$$\text{Percent frequency} = (S/T) \times 100 \quad (2)$$

ORIGINAL PAGE IS
OF POOR QUALITY

where S is the number of cases within the critical crosswind interval and T is the total number of wind observations for that time interval. These runway crosswind percentage frequencies are given by month in Tables 1.1 through 13.1 for each 3 h period of the day. Finally, statistical tables involving the concurrent use of both runways were developed. These may give more meaningful information if a landing can be made on either of the two runways. For example, if a particular wind observation resulted in a 20 knot crosswind component on runway 17 but only 13 knots on runway 24, the more favorable (or minimum) crosswind component of 13 knots was used to develop these statistics.

2. Tailwind Procedure. In addition to critical crosswinds adversely affecting the landing of space vehicles and aircraft, headwind reversals (i.e., a headwind changing to a tailwind) also can present problems. Given in this section are percent frequency of occurrence tables that pertain to critical tailwind and tailwind/crosswind speeds. The crosswind computations discussed in the last section of this report do not require a specification of the landing direction since a wind component is calculated normal to the runway. This means that a critical crosswind that affects the vehicle from either the left or right side is tallied. However, in analyzing headwinds and tailwinds, the direction of the component parallel to the runway is important. If, for example, it were necessary to land on either runway 17 or 22 (from northeast), a wind component from the northeast (a tailwind) would be unfavorable. In the computations performed here, parallel runway winds were computed using the following formula:

$$\text{Parallel wind} = \{ \cos | \text{WD} - \text{RA} | \times \text{WS} \} \quad (3)$$

where

RA = runway angle measured from true north

WD = wind direction in degrees clockwise from true north

WS = wind speed in knots.

When computing a parallel runway wind, sign is important. If equation (3) gives a positive velocity (+), it defines a tailwind. Conversely, a negative velocity (-) defines a headwind. Critical tailwind interval limits of 1-4, 5-9, and 10-up knots were used by hour and month in computing the runway tailwind probabilities as given in Tables 1.2 through 13.2. Finally, crosswind-versus-tailwind percentages are given in Tables 1.3 through 13.3 by month and hour for each runway.

3. Headwind Reversal Procedure. In this analysis of runway headwind components an attempt has been made to answer some basic questions concerning 1 h wind reversal frequencies. For example, (1) What is the probability that the wind component parallel to the runway will reverse direction? (2) Do reversals from northeast to southwest components occur as frequently as southwest to northeast changes? (3) Suppose the wind direction at some specified time is known; what then is the conditional probability of a reversal?

a. **Frequency of Wind Reversals.** To calculate this value it is only necessary to count those cases when the parallel wind component switches from one hour to the next; i.e., if the component goes from (+) to (-) or from (-) to (+), this indicates a switch and is tallied. Dividing this tally by the entire hourly data sample gives a percent frequency (occurrence rate) of the wind reversing on the runway over that time interval. This procedure is expressed in equation (4) as follows:

$$X(I,J) = \frac{100Y(I,J)}{Z(I,J)} \quad (4)$$

where

$X(I,J)$ = percent frequency of parallel component wind reversal for month I and time period J

$Y(I,J)$ = number of occurrences of parallel wind reversals during month I and time period J

$Z(I,J)$ = total observations during month I and time period J .

The reversal tallies were entered on the resulting hour; i.e., a reversal wind between 0700 and 0800 LST is entered at 0800 LST (the resulting time). However, since hours are combined into time intervals, this was entered as a tally within the 06-08 3 h time interval. These values are listed in column 1 (TOTAL) of Tables 1.4 through 13.4A.

b. **SW to NE and NE to SW Reversals.** How often does a southwest wind component reverse to a northeast wind component from 1 h to the next? To compute these reversals, the number of southwest to northeast component changes are tallied and then divided by the total number of observations for that time period. These values appear in column 2 (HEAD-TAIL) of Tables 1.4 through 13.4A for runways 17 and 22 but in column 3 (TAIL-HEAD) for runways 35 and 4. Wind component changes from northeast to southwest are calculated in the same way.

c. Conditional Wind Reversals. Given a southwest parallel component wind initially, how often does this southwest wind change into a northeast wind component by the next hour? This third question deals with the conditional statement that given a southwest wind, what is the probability of its changing into a northeast wind; i.e., $P(NE|SW)$. In this third question we must look at only the hourly southwest components in the data sample and then tally the southwest to northeast wind changes over an hour. This tally must be divided by the number of southwest wind components in the sample, not by the total data sample, because prior knowledge of the wind direction is assumed (i.e., southwest winds are set as given initially). See columns 4 and 5 of Tables 1.4 through 13.4A. Likewise, column 5 presents the conditional percentage frequency of a northeast to southwest reversal by using the same method.

In this section the following conditional probability equation was used:²

$$P(X|Z)_{ij} = \frac{100 Y(I,J)}{Z(I,J)} \quad (5)$$

where

$P(X|Z)_{ij}$ = conditional probability of the occurrence of a tailwind (X) given a headwind (Z) initially during month I and time J

$Y(I,J)$ = the number of headwind-to-tailwind changes during month I and time period J

$Z(I,J)$ = the total number of headwinds in the month I/time J data sample.

Tables 1.4B through 13.4B also give headwind reversal statistics, but here the statistics are broken out into specified resultant tailwind magnitude categories (i.e., resultant tailwinds of >0-3, 4, 8, >8 knots).

Throughout this headwind reversal section both calm conditions and direct crosswinds were considered as favorable landing conditions.

2. The terminology given here is reversed when considering the probability of a headwind given a tailwind.

E. Explanation of Tables

Tables 1.1 through 13.1, 1.2 through 13.2, and 1.3 through 13.3 of this report are presented as percentages of crosswinds or tailwinds within selected wind speed intervals only. Since probability questions of the type "greater than or equal to a certain value" are usually asked (indicating an accumulative effect), one must add together rows of percentages and, at times, columns as well. Tables 1.4A through 13.4A give the percent of wind reversals for "all" resultant tailwind (or headwind) magnitudes, whereas Tables 1.4B through 13.4B break out the reversal statistics into specified tailwind categories.

The critical crosswind or tailwind speed interval headings, 1 to 4, 5 to 9, etc., are to be interpreted as 1 through 4 knots, 5 through 9 knots, etc. Also, zero crosswinds are classified as all winds that are (1) calm, (2) < 1 knot, and (3) parallel to the runway. Zero tailwinds have not been tabulated, but all tailwinds > 0 knots and < 1 knot were placed within the 1-4 knot classification interval during data analysis. The time intervals given (i.e., 00-02, etc.) indicate eight 3 h intervals, and they are expressed in LST.

1. Crosswind Example. Tables 1.1 through 13.1 give percentages of critical crosswind occurrences within critical crosswind speed intervals versus hour of day for each runway and month. Since runway end number does not matter when computing crosswinds, the runway is listed either as 17-35 or 22-4 on these tables. Examples follow concerning the use of Tables 1.1 through 13.1 in which crosswind occurrence percentages can be easily calculated by summing up percentages in the appropriate row. For runway 17-35 between hours 00-02 for the April reference period, Table 4.1A gives a 40.10 percent chance of encountering a crosswind ≥ 5 knots. One must add $24.49 + 11.62 + 3.59 + 0.30 + 0.10 = 40.10$. This also means that 59.9 percent (i.e., $45.15 + 14.75 = 59.9$) of the crosswinds are < 5 knots. Similarly, crosswind percentages ≥ 20 knots can be computed for all hours on runway 17-35 by adding, on the 00-23 line (under HRS), $1.96 + 0.33$ to arrive at a percentage of 2.29. In this same category, zero crosswinds (calm conditions, crosswinds < 1 knot, or winds parallel to the runway) occur 17.72 percent of the time.

Table 4.1B gives similar formatted results for runway 22-4. This is, one can expect an 18.69 percent occurrence rate of April crosswinds ≥ 5 knots between hours 00-02. Runway 22-4 experiences lower crosswind percentages for these given criteria of speed, hour, and month.

Table 4.1C again gives similar results, but here runways 17-35 and 22-4 were checked simultaneously when making tallies of crosswinds. The tables

ORIGINAL PAGE IS
OF POOR QUALITY

were compiled from the lesser of the two crosswind components. These values apply when the aircraft has the capability to land on either of the two runways and can, therefore, choose the one with the least critical conditions existing at the time of landing. The percentage of critical crosswinds ≥ 5 knots during April, between 00-02 hours, for both runways is 11.87 (i.e., $8.69 + 2.42 + 0.66 + 0.10 = 11.87$). As expected, the percentage is much lower here than that for either runway 17-35 (40.1 percent in Table 4.1A) or runway 22-4 (18.69 percent in Table 4.1B) computed individually.

2. Tailwind Example. Tables 1.2 through 13.2 give percentage frequencies of tailwind components within critical tailwind speed intervals versus hour of day for each runway heading and month. Since landing direction does play a part in the computation of tailwinds (or headwinds), the runways are listed as 17, 35, 22, and 4, indicating the approach direction (i.e., 17 is landing into 170 degrees from the northeast end of the runway). Some examples follow that indicate the use of Tables 1.2 through 13.2. Again, the format of the tables is similar to that of Tables 1.1 through 13.1, and the tailwind statistics presented are not accumulated. The April tailwind percentage ≥ 5 knots between 00-02 hours LST for runway 17 as presented on the left side of Table 4.2A is 2.32 ($1.87 + 0.45 = 2.32$). The companion table of 4.2A indicates a tailwind percentage of 42.52 for runway 35 for the same specified conditions. The 42.52 percent on runway 35 can also be interpreted as the percentage of headwinds on runway 17. A tailwind on one runway heading (35) is a headwind on the other end of the runway (17). Combined percentiles for all hours can be obtained from the 00-23 row.

Tables 1.3 through 13.3 give percentages for the joint occurrence of winds within selected crosswind versus tailwind speed intervals. These monthly tables are presented for each end of the runway and are displayed by hour of day (LST). Tables 1.3 through 13.3 offer the advantage of obtaining percentages by choosing the critical crosswind and tailwind limits concurrently, not separately. That is, suppose both crosswinds and tailwinds ≥ 5 knots are critical to a landing operation for 00 hours during April on runway 17, one would find the intersection number that pertains to the intervals of crosswind 5-9 and tailwind 5-9. In this case, the number in Table 4.3 is 0.45 percent. This is not the percentage number needed since these table percentages, again, are not accumulated. Therefore, one must sum all the tailwind rows ≥ 5 knots that encompass all crosswind values ≥ 5 knots. This will satisfy the required condition. Figure 5 illustrates the Table 4.3 example in more detail in that the percentage numbers to be added are enclosed by dashed lines. The total required sum of these ten numbers is 1.5, which is the required percentage.

Since Tables 1.3 through 13.3 are the most involved of the tables presented thus far, a few notes of caution are issued that one should remember while using them. The total row and column offer a sum of all rows or columns, respectively. The total column (of Tables 1.3 through 13.3) has also added into it all the zero crosswind percentages. The percentage numbers enclosed by stars in Figure 5 show the percent frequency of tailwinds without regard to crosswind components. An example of using the total row follows. If one needs the percentage of all crosswinds ≥ 5 knots on runway 17 at 00 hours in April which encompasses all tailwind categories, he can sum the numbers 3.48, 1.06, 1.21, 0.30, and 0.00 to arrive at 6.05 percent. Why is this value so much less than the 40.1 00-02 hour percentage of crosswinds ≥ 5 knots on runway 17-35 from Table 4.1A? The answer is that the 6.05 percent corresponds to crosswinds ≥ 5 knots with regard to all tailwind categories. Tables 1.1 through 13.1 give crosswinds ≥ 5 knots with regard to all parallel winds (tail and head combined). To obtain comparable numbers, one must calculate from Table 4.3 the crosswind percentage ≥ 5 knots (37.41 percent) with regard to all tailwinds on runway heading 35 (a headwind on runway 17) and add the two percentages (6.05 + 37.41) to arrive at 43.46 percent, which corresponds closely to Table 4.1 values. The numbers will not be exact because Tables 1.1 through 13.1 and 1.2 through 13.2 give statistics in 3 h groups, while Tables 1.3 through 13.3 are by each individual hour. Both tailwinds and headwinds from Tables 1.3 through 13.3 may have to be used depending upon the application.

Runway 17, Hour 0, Edwards AFB, April

Tailwind Limits	Crosswind Limits						Zero

OF POOR QUALITY

3. Headwind Reversal Example. Tables 1.4A through 13.4A give the percentage of parallel runway wind reversals that answer the three questions posed earlier in this report concerning different runway wind reversal classifications. These tables present the probabilities for each runway end by month and 3 h time period. Column 1 answers question 1 and gives the total reversals for all observations (within time and month category). Columns 2 and 3 answer question 2 by giving the percent frequency of headwind-to-tailwind and tailwind-to-headwind reversals, respectively, for all observations. Question 3 on conditional probability is answered in columns 4 and 5. It should be pointed out that the statistics presented in Tables 1.4A through 13.4A deal with the probability of reversals without regard to the resulting parallel-wind magnitude classification, as presented in Reference 1. This means, for example, that the columns regarding headwind-to-tailwind reversals (columns 2 and 4) were computed for all resultant tailwind components. On the "A" tables, all magnitudes of the resultant tailwinds were combined before the statistics were computed. However, Tables 1.4B through 13.4B present these same reversal statistics with respect to different categories of the resultant tailwind magnitudes.

These statistics should prove valuable to both the mission planner and the operational control authority because they are based upon a prior knowledge of the wind-type information that will be available during the mission. For example, consider a landing planned for 1000 LST in April on runway 17. Assume that the wind observed at 0900 LST is known to have a headwind component along that runway. Table 4.4A, column 4, indicates that 18.34 percent of those wind observations changed to such an extent that at the following hour (1000 LST) there was a tailwind component on runway 17. This percentage can also be obtained from the appropriate total column of Table 4.4B. Restated in terms of risk: with a known headwind component at 0900 LST, the risk of change to a tailwind component at 1000 LST is approximately 18 percent. Of course, this risk statement does not consider the forecast capability that would be utilized in the real-time operation.

If the investigator were interested in the percent of headwind reversals of all reversals which resulted in a tailwind of ≥ 4 knots, this can be obtained from Table 4.4B by adding 4.02 and 0.49 to arrive at 4.51 percent.

F. Headwind Components

Tables 1.5 through 13.5 give cumulative percentage frequencies of headwind components along each runway during the daytime hours. These tables were computed by equation (3), using only those wind observations that displayed a headwind component along the specified runway. This means that for the runway 17 computations, for example, all observations of wind directions from

approximately west through north to east (tailwind components) were eliminated. This accounts for the lower number of total observations. The component speed column should be interpreted as follows: 0-1 includes speeds from 0 to 0.9 knots; 1-2 contains values from 1.0 to 1.9 knots, etc. Calms are included in the zero category.

The use of the tables is illustrated by the following example: "What is the risk of a headwind component ≥ 15 knots on runway 17 at 12-14 hours in April?" Table 4.5A shows that 92.02 percent of the headwind observations were ≤ 14.9 knots. Conversely, there is a 7.98 percent risk of speeds ≥ 15 knots. "What is the 95 percentile headwind component speed from the same table?" Interpolation between 94.81 and 96.05 for 95 results in a speed of approximately 17 knots.

IV. NORMAL PROBABILITIES FOR EDWARDS AFB WIND COMPONENTS - ALTITUDE 0 THROUGH 27 km

This section presents bivariate normal wind statistics for Edwards AFB for altitudes 0 through 27 km. The bivariate normal statistics for all months for the 90 degree flight azimuth are given in Tables 1.6 through 12.6. The standard meteorological notation for this flight azimuth defines u as the zonal wind component and v as the meridional wind component. The sample estimates of the theoretical mean u are $\bar{u}$ and $\bar{v}$. The sample estimates of the theoretical standard deviation σ are $S(u)$ and $S(v)$. $R(uv)$ is the sample estimate of the theoretical correlation coefficient between u and v . $S(uv)$ is the covariance of u and v , and N is the sample size. The five statistics $\bar{u}$, $\bar{v}$, $S(u)$, $S(v)$, and $R(uv)$ completely define a bivariate normal elliptical distribution. From these five parameters the probability distributions described by Smith [5] and the statistics for any rotation of axes by Falls [6] can be computed.

Since Edwards AFB was not part of the Upper Air Network, winds-aloft observations in support of test activities were made at irregular intervals rather than at regular synoptic times. Because of the time and altitude variation between observations it was not feasible to make them serially complete. As a result, the number of observations decreases rapidly as altitude increases. If wind statistics for altitudes above 27 km are needed, it is recommended that those applicable to Vandenberg AFB, as given in Reference 7, be used. For the reader's interest, Cape Kennedy normal probabilities for wind components have also been computed [8].

V. CONCLUSION

In summary, this report provides two different types of wind statistics applicable to the Edwards AFB area.

First, ground-level wind statistics are given computed with regard to the two Edwards AFB runway orientations. Crosswinds, tailwinds, and headwind reversals are the parameters computed by critical class intervals for hour, month, and runway. If cumulative percentage results are needed, one must follow the procedures given in this report and accumulate the appropriate percentages. Also, since a peak wind sample was not available for this study, the standard type of on-the-hour averaged observations were used. It has been determined that a multiplication factor of 1.4 can be used directly on these wind speed statistics to approximate peak wind statistics. Peak winds are generally more useful in design and operations.

Second, winds-aloft information is presented from 0 through 27 km altitude. Bivariate normal wind statistics involving wind probability distributions and statistics for any rotation of axes can be computed from the five given statistical parameters, $\bar{u}$, $\bar{v}$, $S(u)$, $S(v)$, and $R(u, v)$ for a 90 degree flight azimuth.

Further climatological information involving the Edwards AFB area can be obtained from References 9 through 11.
